

# ELECTRIC FIELD INDUCED IN THE MAGNETOSPHERE DURING STRENGTHENING OF THE SOLAR WIND PRESSURE

Yu.P. Maltsev (*Polar Geophysical Institute, Apatity, 184200, Russia*)

Fast jump in the solar wind pressure known as a sudden impulse (SI) produces the induction electric field in the magnetosphere. In a two-dipole model the field is

$$\mathbf{E} = -[\mathbf{v}_1 \times \mathbf{B}_1] - \nabla\varphi \quad (1)$$

where  $\mathbf{v}_1$  and  $\mathbf{B}_1$  are the velocity and magnetic field of the imaginary dipole respectively,  $\varphi$  is the electric potential which may be calculated with help of the high conductivity condition

$$(\mathbf{E} \mathbf{B}) = 0 \quad (2)$$

where  $\mathbf{B} = \mathbf{B}_E + \mathbf{B}_1$  is the total magnetic field,  $\mathbf{B}_E$  is the field of the earth dipole. Substituting (1) to (2) and considering the earth to be small, we get

$$\varphi = \int_0^{\mathbf{r}} \frac{(\mathbf{v}_1 [\mathbf{B}_E \times \mathbf{B}_1])}{B^2} (\mathbf{B} d\mathbf{r}) \quad (3)$$

where  $\mathbf{r}$  is the distance from the earth dipole.

Assuming, as the first approximation,  $B_1 \ll B_E$ ,  $r \ll a$ , where  $a$  is the distance to the imaginary dipole, we obtain in the equatorial plane  $\varphi = v_1 B_{1zo} y (1 + 3x / 2a)$ , where  $B_{1zo} = B_{1z}(\mathbf{r} = 0)$ . Substitution of  $\varphi$  into (1) yields the radial and azimuthal electric field components (the  $\lambda$ -axis is directed eastward)

$$E_\rho = 0, \quad E_\lambda = -\frac{\rho}{2} \frac{\partial B_{1zo}}{\partial t} \quad (4)$$

The azimuthal electric field drives the magnetospheric plasma drift with the radial velocity  $v_\rho = E_\lambda / B_z$ . Magnetic field in the frame of a frozen-in plasma varies as follows

$$\frac{dB_z}{dt} = \frac{\partial B_z}{\partial t} + v_\rho \frac{\partial B_z}{\partial \rho} \quad (5)$$

Substituting  $v_\rho$  and (4) into (5), and accounting for  $\delta B_z / \delta \rho = -3B_z / \rho$ , we get

$$\frac{dB_z}{dt} = \frac{5}{2} \frac{\partial B_z}{\partial t} \quad (6)$$

Thus, the betatron acceleration of the frozen-in plasma is 2.5 times stronger if the induction electric field is taken into consideration.
